(54) Reversible multi-color thermal recording medium

- (57) A reversible multi-color thermal recording medium comprises, laminated on a substrate:
 - (i) an irreversible thermal composition comprising a colorless or pale basic achromatic dye and an organic irreversible heat-resistant color developer; and
- (ii) a reversible multi-color thermal composition comprising a colorless or pale basic achromatic dye and an organic reversible heat-resistant color developer.

Background of the Invention

This invention relates to a reversible multi-color thermal recording medium which is free from color development of its ground when an image is formed or erased, has high sensitivity and provides a vivid color tone.

Thermal recording sheets are generally prepared by the following method. A colorless or pale basic achromatic dye and an organic developer made from a phenolic substance or the like are ground into fine particles and dispersed, and the resulting dispersions are mixed together. To the resultant mixture are added a binder, a filler, a sensitizer, a lubricant and other auxiliaries to prepare a coating fluid. The coating fluid is applied to a support such as paper, synthetic paper, film, plastic or the like to produce a thermal recording sheet. Color development recording is effected by an instantaneous chemical reaction caused by heating with a hot pen, a thermal head, a hot stamp, a laser beam or the like.

These thermal recording sheets are now applied in a wide range of fields such as measuring recorders, terminal printers for computers, facsimiles, automatic ticket vending machines, bar code labels and the like. Along with recent progress in the diversification and the improvement of performance of these recording apparatuses, higher quality is required for the thermal recording sheets. For instance, along with an increase in the speed of recording, the thermal recording sheets are required to obtain high-density and clear color images with extremely small heat energy. Further, the thermal recording sheets are required to be excellent in keeping quality such as light resistance, weather resistance and oil resistance.

On the other hand, due to a sharp increase in the consumption of information recording media resulted by the construction of a variety of networks and the popularization of facsimiles and copiers, waste disposal is becoming a social problem. As one of solutions to this problem, much attention is paid to recording media having reversibility, that is, so-called reversible recording media which allow for repetitions of recording and erasure.

The reversible recording media have been disclosed such as recording media in which a recording material changes between transparent and opaque reversibly according to given temperature, recording media which make use of reversibility of a thermochromic material, recording media which make use of reversible changes in the color tone of a leuco dye, and the like.

The reversible recording media in which a recording material changes between transparent and opaque reversibly are disclosed in Japanese Patent Publication Nos.54-119377, 63-39377, 63-41186, 3-230993 and 4-366682. However, these reversible recording media have such defects as lack of image sharpness, slow decolorization speed and need for temperature control upon erasure.

The reversible recording media making use of a thermochromic material involve the problem that most of thermochromic materials have poor data storage ability and require continuous heat supply to keep color development.

Meanwhile, the reversible recording media making use of reversible changes in the color tone of a leuco dye are disclosed in Japanese Patent Publication Nos. 60-193691, 60-257289 and the like. However, these recording media effect decolorization with water or steam and have problems with practical application. Further, Japanese Patent Publication Nos. 2-188293 and 2-188294 disclose a simple layer-structured material (color developing and subtracting agent) which has both color developing and subtracting functions to provide reversible changes in the color tone of a leuco dye only by controlling heat energy. However, with this color developing and subtracting agent, satisfactory color density cannot be obtained because decolorization process already starts in process of color development. Further, decolorization cannot be accomplished. For this reason, satisfactory image contrast cannot be obtained.

A heated roll which is controlled to a specific temperature is used to erase an image on a reversible recording medium making use of reversible changes in the color tone of a leuco dye. Since a reversible developer used in the reversible recording medium has no heat resistance, the ground of the medium markedly develops a color through heated roll treatment.

As described above, the reversible recording media of the prior art which make use of a reaction between a color coupler and a color developer involve various problems and are still unsatisfactory.

Meanwhile, there have been great needs for multi-color recording media, and double-color thermal recording paper for use in labels, coupon tickets, video printers and the like has been implemented. This thermal recording paper is structured such that it is a laminate consisting of a support and high-temperature and low-temperature color developing layers formed on the support which develop colors with different color developing energies and two different methods have been proposed. One of them is to obtain a color of an image obtained when the high-temperature color developing layer develops a color as an intermediate color between a color developed only by the high-temperature layer and a color developed only by the low-temperature layer without discoloring an image of the low-temperature color-developing layer which develops a color when the high-temperature color developing layer develops a color. In this case, a double-color image having good contrast cannot be obtained unless a color developed by the high-temperature color developing layer thoroughly. It is impossible to form a double-color image if a color developed by the low-temperature color developing layer is black.

The other method is to erase a colored image of the low-temperature color developing layer which develops a color simultaneously with the color development of the high-temperature color developing layer, using an appropriate decolorizing agent. In this case, combinations of developed colors are arbitrary. However, since compatibility between color developing property and decolorization property is hard to be obtained, a satisfactory decolorization agent is yet to be discovered.

Summary of the Invention

It is therefore an object of the invention to provide a reversible multi-color thermal recording medium which is free from color development of its ground when an image is formed or erased, has high sensitivity, and provides a vivid color tone.

This invention has been made to solve the above problems by using an irreversible heat-resistant color developer as an organic color developer contained in an irreversible thermal composition and a reversible heat-resistant color developer as an organic color developer contained in a reversible thermal composition in a reversible multi-color thermal recording medium prepared by laminating the irreversible thermal composition containing a colorless or pale basic achromatic dye and the organic color developer as main components and the reversible thermal composition containing a colorless or pale basic achromatic dye and the organic developer as main components on a support.

In concrete terms, a compound represented by the following general formula (I) or (I') is used as the reversible heat-resistant color developer and at least one of compounds represented by the following general formulae (II), (III), (IV) and (V) is used as the irreversible heat-resistant color developer.

$$R - NH - C - NH - OH \qquad \cdots \qquad (1)$$

In the above formula (I), X is selected from the group consisting of a hydrogen atom, alkyl group having 1 to 12 carbon atoms, halogenated alkyl group having I to 3 carbon atoms, alkoxy group having 1 to 12 carbon atoms, alkoxycarbonyl group having 1 to 12 carbon atoms, acyl group having 1 to 12 carbon atoms, dialkylamino group having 1 to 12 carbon atoms, nitro group, cyano group and halogen atom, m is an integer of 1 to 12, and n is an integer of 1 to 3.

In the above formula (I'), R is an alkyl group having 12 to 22 carbon atoms, A is selected from the group consisting of a lower alkyl group, lower alkoxy group, lower alkoxycarbonyl group, nitro group, halogen atom and hydrogen atom, and n is an integer of 1 to 3.

$$X_{m} \xrightarrow{\hspace{1cm}} N - C - N - \left(\begin{array}{c} \\ \\ \\ \\ \end{array} \right) - SO_{2} - NH_{2} \qquad \cdots (II)$$

In the above formula, X is selected from the group consisting of a lower alkyl group having 1 to 4 carbon atoms, alkoxy group having 1 to 3 carbon atoms, hydrogen atom, nitro group, cyano group and halogen atom, and m is an integer of 1 to 3.

In the above formula, X, R1, R2, R3, R4, R5, R6, R7 and R8 are independently selected from the group consisting of a lower alkyl group having 1 to 6 carbon atoms, alkoxy group having 1 to 6 carbon atoms, hydrogen atom, nitro group, cyano group and halogen atom, and m is an integer of 1 to 3.

$$\begin{array}{c} X_{n} \\ \downarrow \\ HO \end{array} \longrightarrow \begin{array}{c} O \\ \parallel \\ -NH - C - NH - (CH_{2})_{m} - NH - C - NH - (IV) \\ \downarrow \\ OH \end{array} \qquad \cdots \qquad (IV)$$

in the above formula, X is selected from the group consisting of a lower alkyl group having 1 to 6 carbon atoms, alkoxy group having 1 to 6 carbon atoms, nitro group, halogen atom and hydrogen atom, m is an integer of 1 to 12, and n is an integer of 1 or 2.

$$X_{n} \xrightarrow{Q} -NH - \stackrel{Q}{C} - NH - \stackrel{Q}{Q} - Z - \stackrel{R}{Q} \xrightarrow{R_{2}} \cdots (V)$$

In the above formula, X is selected from the group consisting of an alkyl group having 1 to 12 carbon atoms, alkoxy group having 1 to 12 carbon atoms, trihalogenated methyl group, hydrogen atom, nitro group and halogen atom, Z is selected from the group consisting of O, S, straight chain having 1 to 12 carbon atoms, branched alkylene group, NH, SO 2 and C=O, R1, R2 and R3 are independently selected from the group consisting of an alkyl group having 1 to 6 carbon atoms, hydrogen atom, nitro group and halogen atom, and n is an integer of 1 to 3.

As for erasure of an image on the reversible thermal recording medium, various methods are conceivable such as one in which temperature and the amount of heat lower than those at the time of recording are given with a thermal head, a hot stamp, a heated roll or the like for erasure, one in which the amount of light smaller than that at the time of recording is irradiated by a laser, a halogen lamp or the like for erasure, and one in which the ground of a recording medium is brought into contact with a low-boiling alcohol solvent such as methanol and ethanol for erasure. Particularly, a heated roll controlled to 100 to 150 °C is easily used from a view point of operational ease. In this case, since the reversible recording composition and the irreversible recording composition are treated with a heated roll at the same time, a heat-resistant color developer needs to be used to prevent both of the reversible recording composition and the irreversible recording composition from developing colors from their grounds.

Further, as for the order of laminating the reversible recording composition and the irreversible recording composition onto a support, the support, the irreversible recording composition and the reversible recording composition may be laminated in the order named, or the support, the reversible recording composition and the irreversible recording composition may be laminated in the order named. Or two or more layers of the reversible recording composition and the irreversible recording composition may be laminated together.

In the present invention, since the hue of an image obtained by first recording or erasure is made different from the hue of an image recorded next by using a combination of the irreversible recording composition and the reversible recording composition, it is possible to find whether an recorded image is additionally recorded or not.

Illustrative examples of the irreversible heat-resistant color developer used in combination with the leuco dye in the reversible multi-color thermal recording medium of the present invention include the following urea compounds and thiourea compounds. However, the color developer of the present invention is not limited to these.

In the present invention, as a sensitizer, an aliphatic amide such as amide stearate or amide palmitate, ethylene bisamide, montan wax, polyethylene wax, dibenzyl terephthalate, p-benzyl oxybenzyl benzoate, di-p-tolylcarbonate, p-benzyl biphenyl, phenyl α -naphthyl carbonate, 1,4-diethoxy naphthalene, 1-hydroxy-2-phenyl naphthoate, 1,2-di-(3-methylphenoxy)ethane, oxalic acid di(p-methylbenzyl), β -benzyloxynaphthalene, 4-biphenyl-p-tolylether, O-xylylene-bis-(phenylether), 4-(m-methylphenoxymethyl)biphenyl or the like may be added within the range that does not impair the effect of the invention.

In the present invention, when a plurality of reversible thermal recording layers and irreversible thermal recording layers are provided to prepare a multi-color recording medium, an intermediate layer of a resin is preferably interposed between the recording layers to be laminated together. The resin intermediate layer is intended to prevent the recording layers from being mixed together during heating and can be formed by applying a resin which does not melt at a recording temperature to the recording layers to be laminated together. The resin usable in the present invention may be of the same kind as a binder resin used in adjacent recording layers, but is preferably incompatible with the binder resin. Illustrative examples of the resin include polyvinyl alcohol, polyacrylamide, polyacrylate and polyamide resins and the like, but the resin is not limited to these. A multi-color thermal recording medium providing a vivid color tone can be obtained by providing a resin intermediate layer.

The resin intermediate layer may be thick enough not to be broken by application of heat and pressure due to repetitions of recording and erasure. If the resin intermediate layer is too thick, thermal conductivity deteriorates. Therefore, the thickness of the intermediate layer is preferably as small as possible and typically 10 μ m or less.

The intermediate layer of the present invention may contain a filler. The filler used in the invention may be an organic or inorganic filler such as silica, calcium carbonate, kaolin, baked kaolin, diatomaceous earth, talc, titanium oxide or aluminum hydroxide. The weight ratio of the filler to the resin both constituting the intermediate layer is preferably 2:1 to 20:1.

Illustrative examples of the binder used in the reversible thermal recording layer and the irreversible thermal recording layer of the present invention include denatured polyvinyl alcohols such as wholly saponified polyvinyl alcohols having a polymerization degree of 200 to 1,900, partly saponified polyvinyl alcohols, carboxy-denatured polyvinyl alcohols, amide-denatured polyvinyl alcohols, sulfonic acid-denatured polyvinyl alcohols, butyral-denatured polyvinyl alcohols and other denatured polyvinyl alcohols, hydroxyethyl cellulose, methyl cellulose, carboxymethyl cellulose, styrene-maleic anhydride copolymer, styrene-butadiene copolymer and cellulose derivatives such as ethyl cellulose and acetyl cellulose, polyvinyl chloride, polyvinyl acetate, polyacrylamide, polyacrylate, polyvinyl butyral polystyrol and copolymers thereof, polyamide resins, silicon resins, petroleum resins, terpene resins, ketone resins and cumarone resins. These high molecular substances may be dissolved in a solvent such as water, alcohol, ketone, ester or hydrocarbon, emulsified in water or other solvent, or dispersed like a paste, and may be combined in accordance with required quality.

The filler used in the reversible thermal recording layer and the irreversible thermal recording layer of the present invention may be an organic or inorganic filler such as silica, calcium carbonate, kaolin, baked kaolin, diatomaceous earth, talc, titanium oxide and aluminum hydroxide.

In addition to these, a release agent such as an aliphatic acid metal salt, a lubricant such as wax, a water-proof agent such as glyoxal, a dispersant, an anti-foaming agent and the like can be contained in the recdrding layers.

Further, an overcoat layer of a high molecular substance containing a filler may be formed on a thermal color developing layer for the purpose of improving keeping quality.

Moreover, an undercoat layer containing an organic or inorganic filler may be formed under the thermal color developing layer for the purpose of improving keeping quality and sensitivity.

The above organic color developer, basic achromatic dye and materials added as required are ground with a grinder such as a ball mill, attritor or sand grinder or an appropriate emulsifier until a particle diameter of 1 μ m or less is achieved. The resulting particles are mixed with a binder and various additives according to application purpose to prepare a coating fluid.

The amounts of the organic color developer and the basic achromatic dye used in the present invention and the kinds and amounts of other components are determined according to required performance and recording quality and

not limited particularly. Typically, 1 to 8 parts of the organic color developer and 1 to 20 parts of the filler are used based on 1 part of the basic achromatic dye and 10 to 25% of the binder is used based on the total solid content.

To fabricate the reversible multi-color thermal recording medium of the present invention, the thermal coating fluid and the intermediate layer coating fluid having the above compositions are applied alternately to a desired support such as paper, synthetic paper, plastic film or nonwoven fabric and dried to prepare a multi-layered laminate. In this way, the reversible multi-color thermal recording medium of interest can be obtained.

A light absorbent which absorbs light with its thermal recording layer or the like and converts it into heat can be contained in the reversible multi-color thermal recording medium of the present invention to produce an optical recording medium. The light absorbent used in the recording medium of the present invention to convert light into heat may be any kind of substance provided it absorbs the wavelength of light coming from diverse light sources. Various dyes, various pigments, near infrared light absorbents may be used as the light absorbent of the present invention. However, the light absorbent of the present invention is not particularly limited.

When a strobe having a continuous light wavelength is used as a recording light source, for example, a product obtained from a heat reaction between a thiourea derivative and a copper compound as disclosed in Japanese Patent Publication No. 2-206583 and the specification of JP-A-5-30954, graphite, copper sulfide, lead sulfide, molybdenum trisulfide, black titanium and the like as disclosed in Japanese Patent Publication No. 3-86580 may be used as the light absorbent which converts light into heat. In addition to these, carbon black may be used as the light absorbent. These light absorbents may also be used as light absorbents for laser recording.

When a semiconductor laser which is excellent in terms of size, safety, price and modulation is used as a recording laser, particularly when a semiconductor laser having an oscillation wavelength in visible to near infrared ranges is used, examples of a material which absorbs such an oscillation wavelength include polymethine coloring matters (cyanine coloring matters), azulenium coloring matters, pyrylium coloring matters, thiopyrylium coloring matters, squalenium coloring matters, croconium coloring matters, dithiol metal complex salt coloring matters, mercaptophenol metal complex coloring matters, mercaptonaphthol metal complex coloring matters, phthalocyanine coloring matters, naphthalocyanine coloring matters, triallyl methane coloring matters, immonium coloring matters, diimmonium coloring matters, naphthoquinone coloring matters, anthraquinone coloring matters, metal complex salt coloring matters and the like as disclosed in JP-A-54-4142, JP-A-58-94494, JP-A-58-209594, JP-A-2-217287, Japanese Patent Publication No. 3-73814, "Near Infrared Absorbing Coloring Matters" (Chemical Industry No.43 issued in May 1986) and the like.

Illustrative examples of the polymethine coloring matters (cyanine coloring matters) include Indocyanine Green (manufactured of Daiichi Pharmaceutical Co.), NK-2014 (manufactured by Nippon Kanko Shikiso Kenkyujo Co.), NK-2612 (manufactured by Nippon Kanko Shikiso Kenkyujo Co.), 1,1,5,5-tetrakis(p-dimethylaminophenyl)-3-methoxy-1,4-pentadiene, 1,1,5,5-tetrakis (p-diethylaminophenyl)-3-methoxy-1,4-pentadiene and the like. Examples of the squalenium coloring matters include NK-2772 (manufactured by Nippon Kanko Shikiso Kenkyujo Co.) and the like. Examples of the dithiol metal complex salt coloring matters include toluene dithiol nickel complex, 4-tert-butyl-1,2-benzene dithiol nickel complex, bisdithiobenzyl nickel complex, PA-1005 (manufactured by Mitsui Toatsu Senryo Co.), PA-1006 (manufactured by Mitsui Toatsu Senryo Co.), bis(4-ethyldithiobenzyl) nickel complex disclosed in the specification of JP-A-4-80646, bis (4-n-propyldithiobenzyl)-nickel complex and the like. Examples of the immonium coloring matters and the diimmonium coloring matters include IRG002 (manufactured by Nippon Kayaku Co.), IRG022 (manufactured by Nippon Kayaku Co.) and the like. Examples of the anthraquinone coloring matters include IR-750 (manufactured by Nippon Kayaku Co.) and the like. Examples of the anthraquinone coloring matters include IR-750 (manufactured by Nippon Kayaku Co.) and the like. These light absorbents may be used alone or in combination of two or more.

The light absorbent used in the optical recording medium of the present invention may be simply mixed with materials required to produce the optical recording medium. However, as disclosed in Japanese Patent Publication No. 2-217287, the light absorbent is molten and mixed with materials of the light recording medium of the present invention to be dissolved or dispersed in the materials. The materials to be mixed with the light absorbent which is dissolved or dispersed therein include a sensitizer for thermal recording, the color developer of the present invention, a conventional color developer, a dye precursor, a composition comprising a sensitizer for thermal recording and a conventional color developer, a composition comprising a sensitizer for thermal recording and the like.

As for the light absorbent used in the optical recording medium of the present invention, the materials of the optical recording medium of the present invention and the light absorbent are dissolved or dispersed in a solvent in advance, and a mixture of the dissolved or dispersed materials and light absorbent are separated from the solvent for use. The materials which are dissolved or dispersed in the solvent together with the light absorbent are the same as the above materials to be mixed with the light absorbent which is dissolved or dispersed therein.

Further, the light absorbent used in the optical recording medium of the present invention may be co-dispersed (simultaneous mixing and dispersion) with any one of a dye precursor, a color developer and a sensitizer. The light absorbent may also be co-dispersed (simultaneous mixing and dispersion) with a combination of a dye precursor and

a sensitizer or a combination of a color developer and a sensitizer.

10

15

20

25

30

35

40

45

50

55

The light absorbent used in the optical recording medium of the present invention or the light absorbent which is subjected to any one of treatments such as heat-fusion with the above materials, mixing with a solvent and co-dispersion (simultaneous mixing and dispersion) is mixed with thermal recording materials consisting of the color developer of the present invention and a dye precursor as a constituent material of a light absorptive thermal recording layer. The light absorbent may be used as a material for constituting either upper or lower light absorptive layer formed on the thermal recording layer made from the color developer of the present invention and the dye precursor. Further, the light absorbent may be used as a material for constituting both upper and lower light absorptive layers formed on both sides of the thermal recording layer. The light absorbent may be internally added to or impregnated into a support as a material for constituting the light absorptive support. On top of this light absorptive support, the above thermal recording layer or the above light absorptive thermal recording layer on the light absorptive support may be multi-layer structured.

The amounts of the color developer and the dye precursor used in the reversible multi-color optical recording medium of the present invention and the types and amounts of other components are determined according to required performance and recording quality, and are not particularly limited. Typically, 1 to 8 parts of an organic color developer and 1 to 20 parts of a filler are used based on 1 part of the dye precursor and a binder is contained in an amount of 10 to 25% of the total solid content. The amount of the light absorbent added is determined according to its light absorption power.

Further, in the reversible multi-color optical recording medium of the present invention, like the thermal recording medium of the present invention, an overcoat layer of a high molecular substance or the like may be formed on the recording layer of the optical recording medium, or an undercoat layer containing an organic or inorganic filler may be interposed between the recording layer and the support for the purpose of improving keeping quality and sensitivity. The above light absorbent may be added to these overcoat layer and the undercoat layer.

The light absorbent as described above is ground with a grinder such as a ball mill, attritor and sand grinder or an appropriate emulsifier until a particle diameter of 1 μ m or less is achieved and mixed with a binder and various additives according to application purpose to prepare a coating fluid.

As the light source for recording on the optical recording medium of the present invention with light, a variety of lasers such as semiconductor lasers and semiconductor excited YAG lasers, a xenon flash lamp, a halogen lamp and the like may be used. Light irradiated from these light sources may be converged with a light converging means such as a lens for optical recording on the optical recording medium of the present invention. Further, a mirror or the like may be used to carry out optical scanning recording.

Since the reversible multi-color thermal recording medium and reversible multi-color optical recording medium of the present invention have excellent heat resistance and extremely high thermal stability of its ground color, a powerful protective film can be provided by thermal lamination of a plastic film. Therefore, either before or after recording with heat or light, it is possible to easily produce a card having heat resistance and various stabilities, which is protected with a plastic film by means of a film for thermal lamination and a commercial laminator. Particularly, in the case of the optical recording medium of the present invention, additional recording with light can be made on a laminated plastic film. Illustrative examples of the plastic film for thermal lamination include thermoplastic resins such as low-density polyethylene, ethylene-vinyl acetate copolymer (EVA), ethylene-ethyl acrylate copolymer (EEA), ethylene-methyl methacrylate copolymer (EMAA) and ethylene-methacrylate copolymer (EMAA).

Further, extrusion coating is also possible for the reversible multi-color thermal recording medium and reversible multi-color optical recording medium of the present invention, using an extrusion coating resin such as low-density polyethylene which can be extruded at relatively low temperatures.

Moreover, since the reversible multi-color thermal recording medium and reversible multi-color optical recording medium of the present invention is excellent in heat resistance, the grounds of these media do not develop colors even if they contact a toner heat-fixing unit of an electronic photocopier. Therefore, these media can also be used as paper for electronic photocopiers. Thermal recording or optical recording is possible either before or after toner recording with an electronic photocopier.

A description is subsequently given of the mechanisms of color development and decolorization of the reversible multi-color thermal recording medium of the present invention. For instance, in the case of a reversible double-color thermal recording medium, an irreversible thermal composition comprising a basic achromatic dye (developing red color) and an irreversible heat-resistant color developer as main components, an intermediate layer, and a reversible thermal composition comprising a basic achromatic dye (developing black color) and a reversible heat-resistant color developer as main components are laminated on the support in the order named. When heat energy is applied to the reversible multi-color thermal recording medium by a thermal head, a color developing thermal reaction occurs in each layer and a mixture of black and red colors, that is, reddish black color, is obtained. On the other hand, when this color developing recording medium is subjected to heat treatment with a heated roll or thermal lamination, a decolorization reaction is instantaneously caused by the basic achromatic dye (developing black color) and the reversible heat-re-

sistant color developer. As the result, red color developed by the irreversible thermal composition remains.

Further, as for color development and decolorization, a structural change (keto-enol tautomerism) represented by the following formulae may occur in the urea and thiourea derivatives of the present invention depending on conditions. It is considered that these compounds need to have an enol-form structure in order to function as color developers. To cause keto-to-enol tautomerism, high temperatures obtained by a thermal head are required and, at the same time, tautomerism to keto form occurs when an appropriate temperature and an appropriate amount of heat are given, resulting in decolorization.

$$\begin{array}{cccc}
-N-C-N-\\
& \parallel & \parallel & \downarrow \\
& \parallel & \vee & \parallel \\
& \parallel & \vee & \parallel \\
& \text{(Keto-form)} & \text{(Enol-form)}
\end{array}$$

$$Y = 0. S$$

Meanwhile, when a red color developing thermal recording layer, an intermediate layer and a black color developing thermal recording layer are laminated on the support in the order named, using conventional bisphenol A as a color developer, a color developing thermal reaction occurs in each layer with heat energy applied by a thermal head, and reddish black color, a mixture of black and red colors, is obtained. However, when this color developing recording medium is subjected to heat treatment with a heated roll or to thermal lamination, the hue of image portions does not change and reddish black color is markedly developed on the entire ground because bisphenol A is not a reversible heat-resistant color developer.

The reason that the urea and thiourea derivatives which are heat-resistant color developers of the present invention function as color developers for a dye precursor used in thermal recording media and optical recording media, the reason that a thermal recording medium comprising a dye precursor and the color developer of the present invention exhibits extremely high heat resistance, and the reason that an optical recording medium comprising a dye precursor, the color developer of the present invention and a light absorbent can undergo heat treatment with a heated roll or thermal lamination and exhibits extremely high heat resistance are not elucidated yet, but can be considered as follows.

In the case of the above thermal recording, since a thermal head is instantaneously heated to a temperature of 200 to 300 °C, the urea and thiourea derivatives contained in the recording layer of the thermal recording medium which is brought into contact with the thermal head undergo tautomerism to be converted into enol form and to exhibit a color developing function. It is considered that the lactone ring of the dye precursor is thereby cleaved, with the result of color development.

Further, in the case of the above optical recording, since a light absorbent is contained in the optical recording layer, light irradiated from a recording light source is absorbed efficiently and converted into heat by this light absorbent. As the temperature is elevated to 200 to 300 °C instantaneously at this point, the urea and thiourea derivatives contained in the recording layer undergo tautomerism to be converted into enol form and to exhibit a color developing function, as in the above thermal recording. It is considered that the lactone ring of the dye precursor is thereby cleaved with the result of color development.

The urea and thiourea derivatives do not exhibit a color developing function at temperatures at which they do not change into enol form. Since a reaction with the dye precursor does not occur, the color development of the ground does not take place. This seems to be the reason why heat resistance is high. The temperature at which the urea and thiourea derivatives are converted into enol form is considered to be higher than a temperature required for heat treatment with a heated roll and thermal lamination. For this reason, the color development of the ground does not take place in high-temperature thermal environment such as heat treatment with a heated roll and thermal lamination.

Further, in the case of an optical recording medium structured above and subjected to thermal lamination, light irradiated from a recording light source transmits through a plastic film present on the optical recording layer, reaches the light absorbent contained in the optical recording layer, and is converted into heat. Therefore, additional recording is possible even after lamination.

Other and further objects, features and advantages of the invention will become clear from the following description.

The present invention is further illustrated with reference to the following examples. The term "parts" used herein means "parts by weight".

10

15

The above coating fluid was applied to the intermediate layer in a coating weight of 5.0 g/m^2 . The coating was then dried to form a thermal recording layer. This sheet was treated with a supercalender to achieve a smoothness of 600 to 700 seconds so as to prepare a thermal recording sheet.

A quality performance test was made on the thermal recording sheets obtained in the above Examples and Comparative Examples and results are shown in Tables 1 to 3.

Note (1) thermal recording: Using a printer for the Rupo-90FII personal wordprocessor (manufactured by Toshiba), thermal recording was made on the reversible multi-color thermal recording media with the maximum application energy (the same conditions were also employed for thermal recording shown below). The densities of image and ground portions were measured by a Macbeth densitometer (RD-914 with an amber filter, the same conditions were employed hereinafter). Developed color tones were determined visually.

Note (2) decolorization (by a heated roll): The reversible multi-color thermal recording media on which dynamic recording was made by the method of Note (1) were fed through a roll heated to 115 °C at a speed of 7 mm/second and the densities of image and ground portions were measured. As for the ground portions, the smaller the Macbeth density values the more stable the color of the ground portions becomes. Contrast between image and ground portions of a thermally recorded portion which was subjected to heat treatment with a heated roll was evaluated as follows. Thermal recording media whose contrasts were rated Δ to \times are difficult to read.

- O no or almost no color development of ground portions
- Δ color development of ground portions
- × marked color development of ground portions

Note (3) thermal recording: Using a printer for the Rupo-90FII wordprocessor (manufactured by Toshiba), thermal recording was made on color undeveloped portions of reversible multi-color thermal recording media with the maximum application energy after heat treatment with a heated roll. Developed color tones were determined visually.

Comparative Example 4	D-8	D-8	1.32	0.04	-	1.30	1.30	×	=
Comparative Example 5	JK1	JK1	1.33	0.04		1.30	1.30	×	=

Note) Conventional color developers

BPA: bisphenol A

BPS: bisphenol S

POB: p-hydroxy benzyl benzoate

D-8: 4-hydroxy-4'-isopropoxydiphenylsulfone

JK1: 4-hydroxy-4'-butoxydiphenylsulfone

In Examples 1 to 20 and Examples 1' to 20', since a developed color tone changed from reddish black to red upon

erasure with a heated roll, the density of image portions lowered. However, stains were not observed in ground portions. The same tendency was observed in Examples 21 to 40. However, in Comparative Examples 1 to 5, there was no change in the color tone of image portions upon erasure with a heated roll, color development occurred in all the ground portions, and additional thermal recording (3) could not be made because of the absence of color undeveloped portions.

Formation of irreversible thermal recording layer

10 Solution A (dispersion of irreversible heat-resistant color developer)

irreversible heat-resistant color developer (see Tables 4 and 4')	6.0 parts
10% polyvinyl alcohol aqueous solution	18.8 parts
water	11.2 parts

Solution I (dispersion of dye developing green color)

3-(N-p-tolyl-N-ethylamino)-7-(N-phenyl-N-methylamino)fluoran	2.0 parts
10% polyvinyl alcohol aqueous solution	4.6 parts
water	2.6 parts

The solutions having the above compositions were ground to an average particle diameter of 1 μ m with a sand grinder. Subsequently, the resulting dispersions were mixed in the proportion below to prepare a thermal recording layer coating fluid.

solution I	36.0 parts
solution G	9.2 parts
kaolin clay (50% dispersion)	12.0 parts

The above coating fluid was applied to one side of a 50 g/m 2 substrate in a coating weight of 5.0 g/m 2 . The coating was then dried to form an irreversible thermal recording layer.

Formation of intermediate layer

kaolin clay (50% dispersion)	12.0 parts
10% polyacrylamide emulsion	
water	3.0 parts

The solutions having the above compositions were mixed to prepare an intermediate layer coating fluid.

The intermediate layer coating fluid was applied to the above irreversible thermal recording layer in a coating weight of 3.0 g/m². The coating was then dried to form an intermediate layer.

Formation of reversible thermal recording layer

50 Solution D (dispersion of reversible heat-resistance color developer)

	reversible heat-resistant color developer (see Tables 4 and 4')	
	10% polyvinyl alcohol aqueous solution	18.8 parts
<i>55</i>	water	11.2 parts

Solution E (dispersion of dye developing black color)

3-n-dipentylamino-6-methyl-7-anilinofluoran

2.0 parts

10% polyvinyl alcohol aqueous solution 4.6 parts

water 2.6 parts

The solutions having the above compositions were ground to an average particle diameter of 1 μ m with a sand grinder. Subsequently, the resulting dispersions were mixed in the proportion below to prepare a thermal recording layer coating fluid.

solution D	36.0 parts
solution E	9.2 parts
kaolin clay (50% dispersion)	12.0 parts

The above coating fluid was applied to the intermediate layer in a coating weight of 5.0 g/m². The coating was then dried to form a reversible thermal recording layer. This sheet was treated with a supercalender to achieve a smoothness of 600 to 700 seconds so as to prepare a reversible multi-color thermal recording sheet.

[Examples 61 to 80] [Examples 61' to 80']

Formation of irreversible thermal recording layer

Solution A (dispersion of irreversible heat-resistant color developer)

irreversible heat-resistant color developer (see Tables 5 and 5')	6.0 parts
10% polyvinyl alcohol aqueous solution	18.8 parts
water	11.2 parts

Solution J (dispersion of dye developing orange color)

3-cyclohexylamino-6-chlorofluoran 2.0 parts

10% polyvinyl alcohol aqueous solution 4.6 parts

water 2.6 parts

The solutions having the above compositions were ground to an average particle diameter of 1 μ m with a sand grinder. Subsequently, the resulting dispersions were mixed in the proportion below to prepare a thermal recording layer coating fluid.

solution A	36.0 parts
solution J	9.2 parts
kaolin clay (50% dispersion)	12.0 parts

The above coating fluid was applied to one side of a 50 g/m² substrate in a coating weight of 5.0 g/m². The coating was then dried to form an irreversible thermal recording layer. Formation of intermediate layer

Note (4) decolorization (by thermal lamination): A simplified lamination apparatus (MS Pouch H-140 manufactured

by Meiko Shokai K.K.) and a laminate film (MS Pouch Film MP10-6095) were used. A laminated thermal recording medium having a thermal recording portion was fabricated by sandwiching a reversible multi-color thermal recording medium on which dynamic recording was made by the method of Note (1) between the above laminate films at a feed rate of 20 mm/sec. After thermal lamination, image and ground portions which were subjected to the above thermal recording were measured by a Macbeth densitometer through the laminate film of the laminated thermal recording medium (high value because of measurement through the laminate film). As for ground portions, the smaller the Macbeth density value the more stable the color of the ground becomes. Contrast between image portions and ground portions of the laminated thermal recording portion was evaluated as follows. Laminated thermal recording media whose contrasts are rated Δ to \times are difficult to read. In fact, thermal lamination was impossible.

10

35

40

45

50

55

- O no or almost no color development of the ground portions (thermal lamination impossible)
- Δ color development of the ground portions
- × marked color development of the ground portions

In Examples 41 to 80 and Examples 41' to 80', thermal lamination was effected without failure and a change in the color tone of image portions caused by thermal lamination was good. However, in Comparative Examples 6 to 10, there was no change in the color tone of image portions caused by thermal lamination and color development occurred in all the ground portions.

[Examples 81 to 100] [Examples 81' to 100']

25 Formation of irreversible optical recording layer

Solution A (dispersion of irreversible heat-resistant color developer)

irreversible heat-resistant color developer (see Tables 7 and 7')
6.0 parts
10% polyvinyl alcohol aqueous solution
water
11.2 parts

Solution B (dispersion of dye developing red color)

3,3-bis(1-ethyl-2-methylindole-3-yl)phthalide 2.0 parts 10% polyvinyl alcohol aqueous solution 4.6 parts water 2.6 parts

Solution K (aqueous solution of light absorbent)

NK-2612 (manufactured by Nippon Kanko Shikiso Kenkyujo) 0.04 part water 4.0 parts

The solutions having the above compositions were ground to an average particle diameter of 1 μ m with a sand grinder. Subsequently, the resulting dispersions were mixed in the proportion below to prepare an optical recording layer coating fluid.

solution A 36.0 parts
solution B 9.2 parts
solution K 4.04 parts
kaolin clay (50% dispersion) 12.0 parts

The above coating fluid was applied to one side of a 50 g/m² substrate in a coating weight of 5.0 g/m². The

coating was then dried to form an irreversible optical recording layer.

Formation of intermediate layer

5

kaolin clay (50% dispersion)	12.0 parts
10% polyvinyl alcohol aqueous solution	6.0 parts
water	3.0 parts

10

The solutions having the above compositions were mixed to prepare an intermediate layer coating fluid. The intermediate layer coating fluid was applied to the above irreversible optical recording layer in a coating weight of 3.0 g/m². The coating was then dried to form an intermediate layer.

Formation of reversible optical recording layer

Solution D (dispersion of reversible heat-resistant color developer)

reversible heat-resistant color developer (see Tables 7 and 7')	6.0 parts
10% polyvinyl alcohol aqueous solution	18.8 parts
water	11.2 parts

Solution E (dispersion of dye developing black color)

25

20

3-n-dipentylamino-6-methyl-7-anilinofluoran	2.0 parts
10% polyvinyl alcohol aqueous solution	4.6 parts

The solutions having the above compositions were ground to an average particle diameter of 1 μ m with a sand grinder. Subsequently, the resulting dispersions were mixed in the proportion below to prepare an optical recording layer coating fluid.

solution D	36.0 parts
solution E	9.2 parts
solution K	4.04 parts
kaolin clay (50% dispersion)	12.0 parts

The above coating fluid was applied to the intermediate layer in a coating weight of 5.0 g/m². The coating was then dried to form a reversible optical recording layer. This sheet was treated with a supercalender to achieve a smoothness of 600 to 700 seconds so as to prepare a reversible optical recording sheet.

[Comparative Examples 11 to 15]

Formation of optical recording layer

Solution G (dispersion of conventional color developer)

conventional color developer (see Table 8)	6.0 parts
10% polyvinyl alcohol aqueous solution	18.8 parts
water	11.2 parts

Solution B (dispersion of dye developing red color)

3,3-bis(1-ethyl-2-methyl-indole-3-yl)phthalide	2.0 parts
10% polyvinyl alcohol aqueous solution	4.6 parts
water	2.6 parts

Solution K (aqueous solution of light absorbent)

	NK-2612 (manufactured by Nippon Kanko Shikiso Kenkyujo)	0.04 part
5	water	4.0 parts

The solutions having the above compositions were ground to an average particle diameter of 1 μ m with a sand grinder. Subsequently, the resulting dispersions were mixed in the proportion below to prepare an optical recording layer coating fluid.

solution G	36.0 parts
solution B	9.2 parts
solution K	4.04 parts
kaolin clay (50% dispersion)	12.0 parts

The above coating fluid was applied to one side of a 50 g/m 2 substrate in a coating weight of 5.0 g/m 2 . The coating was then dried to form an optical recording layer.

20 Formation of intermediate layer

50

55

kaolin clay (50% dispersion)	12.0 parts
10% polyvinyl alcohol aqueous solution	6.0 parts
water	3.0 parts

The solutions having the above compositions were mixed to prepare an intermediate layer coating fluid. The intermediate layer coating fluid was applied to the above optical recording layer in a coating weight of 3.0 g/m 2 . The coating was then dried to form an intermediate layer.

Formation of optical recording layer

Solution G (dispersion of conventional color developer)

conventional color developer (see Table 8)	6.0 parts
10% polyvinyl alcohol aqueous solution	18.8 parts
water	11.2 parts

Solution E (dispersion of dye developing black color)

3-n-dipentylamino-6-methyl-7-anilinofluoran	2.0 parts
10% polyvinyl alcohol aqueous solution	4.6 parts
water	2.6 parts

Solution K (aqueous solution of light absorbent)

NK-2612 (manufactured by Nippon Kanko Shikiso Kenkyujo)	0.04 part
water	4.0 parts

The solutions having the above compositions were ground to an average particle diameter of 1 μ m with a sand grinder. Subsequently, the resulting dispersions were mixed in the proportion below to prepare an optical recording layer coating fluid.

solution G	36.0 parts
solution E	9.2 parts
solution K	4.04 parts
kaolin clay (50% dispersion)	12.0 parts

The above coating fluid was applied to the intermediate layer in a coating weight of 5.0 g/m^2 . The coating was then dried to form an optical recording layer. This sheet was treated with a supercalender to achieve a smoothness of 600 to 700 seconds so as to prepare an optical recording sheet.

[Examples 101 to 120] [Examples 101' to 120']

Formation of irreversible optical recording layer

Solution L (simultaneous dispersion of irreversible heat-resistant color developer and light absorbent)

irreversible heat-resistant color developer (see Tables 9 and 9')	6.0 parts
bis(1-tert-butyl-3,4-dithiophenolate)nickeltetra-n-butylammonium (light absorbent)	0.3 part
10% polyvinyl alcohol aqueous solution	18.8 parts
water	11.2 parts

Solution F (dispersion of dye developing blue color)

3,3-bis(p-dimethylaminophenyl)-6-dimethylaminophthalide	2.0 parts
10% polyvinyl alcohol aqueous solution	4.6 parts
water	2.6 parts

The solutions having the above compositions were ground to an average particle diameter of 1 μ m with a sand grinder. Subsequently, the resulting dispersions were mixed in the proportion below to prepare an optical recording layer coating fluid.

solution L	36.3 parts
solution F	9.2 parts
kaolin clay (50% dispersion)	12.0 parts

The above coating fluid was applied to one side of a 50 g/m 2 substrate in a coating weight of 5.0 g/m 2 . The coating was then dried to form an irreversible optical recording layer.

Formation of intermediate layer

kaolin clay (50% dispersion)	12.0 parts
10% polyacrylamide emulsion	6.0 parts
water	3.0 parts

The solutions having the above compositions were mixed to prepare an intermediate layer coating fluid. The intermediate coating fluid was applied to the above irreversible optical recording layer in a coating weight of 3.0 g/m ². The coating was then dried to form an intermediate layer.

Note (5) optical recording: Using a laser plotter disclosed in Japanese Patent Publication No.3-239598, laser re-

cording was carried out by the following method. The LTO15MD semiconductor laser (manufactured by Sharp) having an oscillation wavelength of 830 nm and an output of 30 mW was used as a light source for optical recording, and two of the AP4545 non-spherical plastic lens (manufactured by Konica) having an aperture of 0.45 and a focusing distance of 4.5 mm were used as condenser lenses. A laser recording head comprising the above semiconductor laser and lenses was caused to scan at a recording speed of 50 mm/sec and at recording line intervals of 50 μ m to obtain a 1 cm2 solid-colored image. This 1 cm 2 solid-colored image was measured for its density with a Macbeth densitometer (RD-914 using an amber filter) . This value was taken as the optical recording density of image portions. The reason why the values of ground portions are slightly bad in Examples 81 to 120 is that the optical recording media are slightly colored because of the colored light absorbent. In Comparative Examples 11 to 20, decolorization was not caused by thermal lamination and, conversely, marked color development occurred in the ground portions. As the result, additional recording could not be carried out.

Note (6) decolorization (by thermal lamination): A simplified lamination apparatus (MS Pouch H-140 manufactured by Meiko Shokai K.K.) and a laminate film (MS Pouch Film MP10-6095) were used. A laminated optical recording medium having a thermal recording portion was fabricated by sandwiching a reversible multi-color optical recording medium on which optical recording was made by the method of Note (4) between the above laminate films at a feed rate of 20 mm/sec. After thermal lamination, image and ground portions which were subjected to the above optical recording were measured by a Macbeth densitometer through the laminate film of the laminated optical recording medium (high value because of measurement through the laminate film). As for ground portions, the smaller the Macbeth density value the more stable the color of the ground becomes. Contrast between image portions and ground portions of the laminated thermal recording portion was evaluated as follows. Laminated optical recording media whose contrasts are rated Δ to \times are difficult to read. In fact, thermal lamination was impossible.

- O no or almost no color development of the ground portions (thermal lamination possible)
- Δ color development of the ground portions

35

40

45

50

55

× marked color development of the ground portions

Note (7) additional recording: Optical recording was made on optical recording media after thermal lamination by the following method, using flash light from a strobe. Optical recording was effected by stopping down the window of the auto 4330 strobe flash for cameras (manufactured by Sunpack Co.) to 5% and irradiating light. The color developed images were measured for their densities by a Macbeth densitometer (RD-914 using an amber filter). The density values were taken as optical recording densities of the image portions.

In Examples 81 to 120, thermal lamination was carried out after optical recording without failure, a change in the color tone of the image portions caused by thermal lamination was good, and there were no stains in the ground portions. However, in Comparative Examples 11 to 20, there was no change in the color tone of the image portions caused by thermal lamination and color development occurred in all the ground portions. Therefore, additional optical recording (7) could not be carried out.

As described on the foregoing pages, the reversible multi-color thermal recording medium and reversible multi-color optical recording medium of the present invention which use urea and thiourea derivatives as a reversible heat-resistant color developer and irreversible heat-resistant color developer cause almost no fogging of a ground color under temperature environment of up to 160 °C and recording of an image having a vivid color tone and many practical applications is easily effected with a thermal recording apparatus such as a thermal head and an optical recording apparatus using a laser or strobe. Therefore, the present invention has the following effects.

- (1) A reversible multi-color thermal recording medium and a reversible multi-color optical recording medium providing a vivid color tone can be obtained.
- (2) The reversible multi-color thermal recording medium and the reversible multi-color optical recording medium can be used under extreme temperature conditions (90 to 160 C, for example) under which conventional recording media cannot be used.
- (3) Since the reversible multi-color thermal recording medium and reversible multi-color optical recording medium which have recorded images can undergo thermal lamination with a laminator, reversible multi-color thermal recording cards and reversible multi-color optical recording cards can be fabricated with ease.
- (4) Additional optical recording can be made on a laminated reversible multi-color optical recording medium.
- (5) Since the ground colors of the reversible multi-color thermal recording medium and reversible multi-color optical recording medium are stable even if they were fed through a heated roll, they can be used as paper for electronic photocopiers.

Further, in the present invention, since the hue of an image obtained by first recording or erasure is made different from that of an image recorded next by combining a reversible recording composition and an irreversible recording

composition, it is possible to find whether or not a recorded image is recorded additionally, thus making it usable for prevention of forgeries.

50

- 1. A reversible multi-color thermal recording medium which comprises, laminated on a substrate:
 - (i) an irreversible thermal composition comprising a colorless or pale basic achromatic dye and an organic irreversible heat-resistant color developer; and
 - (ii) a reversible multi-color thermal composition comprising a colorless or pale basic achromatic dye and an organic reversible heat-resistant color developer.
- 2. A recording medium according to claim 1, which further comprises an intermediate layer interposed between recording layers which comprise the thermal compositions (i) and (ii).
 - 3. A recording medium according to claim 1 or 2, wherein the reversible heat-resistant color developer has the following formula (I):

$$\begin{array}{c}
O \\
NH - C - NH - (CH_2)_m - NH - C - NH - (CH_2)_m
\end{array}$$
(1)

wherein X is selected from hydrogen, C_1 - C_{12} alkyl, halo- C_1 - C_3 alkyl, C_1 - C_{12} alkoxy, C_1 - C_{12} alkoxycarbonyl, C_1 - C_{12} acyl, C_1 - C_{12} dialkylamino, nitro, cyano and halogen, m is an integer of 1 to 12 and n is an integer of 1 to 3; or the following general formula (I'):

$$R-NH-C-NH \longrightarrow OH \qquad (I')$$

wherein R is C_{12} - C_{22} alkyl, A is selected from lower alkyl, lower alkoxy, lower alkoxycarbonyl, nitro, halogen and hydrogen, and n is an integer of 1 to 3.

4. A recording medium according to any one of claims 1 to 3 wherein the irreversible heat-resistant color developer has a formula selected from the following formulae (II), (III), (IV) and (V):

$$X_{m} \xrightarrow{\qquad \qquad } N - C - N \xrightarrow{\qquad \qquad } SO_{2} - NH_{2}$$
 (II)

wherein X is selected from C_1 - C_4 alkyl, C_1 - C_3 alkoxy, hydrogen, nitro, cyano and halogen, and m is an integer of 1 to 3;

wherein each of X, R_1 , R_2 , R_3 , R_4 , R_5 , R_6 , R_7 and R_8 , which are the same or different, is independently selected from C_1 - C_6 alkyl, C_1 - C_6 alkoxy, hydrogen, nitro, cyano and halogen, and m is an integer of 1 to 3;

55

wherein X is selected from C_1 - C_6 alkyl, C_1 - C_6 alkoxy, nitro, halogen and hydrogen, m is an integer of 1 to 12 and n is 1 or 2;

$$X_{n} \xrightarrow{O} NH \xrightarrow{C} NH \xrightarrow{C} Z \xrightarrow{R_{3}} (V)$$

wherein X is selected from C_1 - C_{12} alkyl, C_1 - C_{12} alkoxy, trihalomethyl, hydrogen, nitro and halogen, Z is selected from O, S, straight chain C_1 - C_{12} alkylene, branched chain C_1 - C_{12} alkylene, NH, SO₂ and C=O, each of R₁, R₂ and R₃, which are the same or different, is independently selected from C_1 - C_6 alkyl, hydrogen, nitro and halogen, and n is an integer of 1 to 3.

- 5. A reversible multi-color thermal recording medium obtainable by laminating a plastic film on a recording medium as defined in any one of the preceding claims, either on the recording surface thereof or on the entire recording medium after thermal recording has occurred.
- **6.** A reversible multi-color optical recording medium which comprises, in a recording layer of a recording medium as defined in any one of claims 1 to 4, a light absorbent for absorbing light and converting it into heat.
- 7. An optical recording medium obtainable by laminating a plastic film on a reversible multi-color optical recording medium as defined in claim 6, either on the recording surface thereof or on the entire recording medium.
 - **8.** An optical recording medium obtainable by laminating a plastic film on a reversible multi-color optical recording medium as defined in claim 6, either on the recording surface thereof or on the entire recording medium after thermal recording or optical recording has occurred.
 - **9.** A method of optical recording, which method comprises applying flash light from a stroboscope or laser light to an optical recording medium as defined in claim 7 or 8.
- 10. A sheet suitable for an electronic photocopier, which comprises a recording medium as defined in any one of claims1 to 4 or an optical recording medium as defined in claim 6.
